Activating Fc $\gamma$  receptors associated with Fc receptor  $\gamma$ -chain (FcR $\gamma$ ) are critical for mediating neutrophil effector functions in immune complex-mediated autoimmune diseases. FcR $\gamma$  contains ITAM tyrosines and the *in vivo* role of these tyrosines has not been defined in neutrophils and arthritis. In this study, the *in vivo* functions of FcR $\gamma$  ITAM tyrosines were characterized using wild type and ITAM tyrosine mutant (Y65F/Y76F) transgenic mice crossed to an FcR $\gamma$ -deficient genetic background. FcR $\gamma$ -deficient neutrophils showed undetectable cell surface expression of the activating Fc $\gamma$  receptor IV, defective immune complex-induced superoxide production, degranulation and spreading. Although the re-expression of both the wild type and the ITAM tyrosine mutant (Y65F/Y76F) FcR $\gamma$  could restore activating Fc $\gamma$  receptor expression of FcR $\gamma$ -deficient neutrophils, only the wild type transgenic form could mediate Fc $\gamma$  receptor-dependent effector functions. In contrast, neutrophils carrying ITAM tyrosine mutant FcR $\gamma$  were unable to produce superoxide, mediate degranulation and perform active spreading. In addition, our results confirmed the protection of FcR $\gamma$ -deficient mice from autoimmune arthritis. Importantly, the presence of the wild type FcR $\gamma$  transgene, in contrast to the ITAM tyrosine mutant transgene, partially reversed autoimmune arthritis development. The reversing effect of the wild type transgene was even more robust when animals carried the wild type transgene in a homozygous form. Collectively, FcR $\gamma$  ITAM tyrosines play a critical role in the induction of neutrophil effector responses, the initiation and progression of an autoantibody-induced experimental arthritis *in vivo*, indicating a signaling, rather than just a receptor stabilizing function of the molecule.

**Keywords:** neutrophils, Fc receptor  $\gamma$ -chain, ITAM tyrosines, autoimmune arthritis, Fc receptors

## INTRODUCTION

Activating Fc $\gamma$  receptors expressed on the surface of neutrophils are critical for mediating various cellular responses including immune complex-triggered cellular activation, clearance of immune complexes and phagocytosis of opsonized particles (1–3). These processes are involved in the pathogenesis of various autoimmune diseases including rheumatoid arthritis (2–4).

Resting human neutrophils express the activating Fc $\gamma$  receptors Fc $\gamma$ RIIA and Fc $\gamma$ RIIIB, while Fc $\gamma$ RI appears upon stimulation (5). While the single chain transmembrane Fc $\gamma$ RIIA contains an immunoreceptor tyrosine-based activation motif (ITAM) in the cytoplasmic tail of the molecule, Fc $\gamma$ RI is associated with an ITAM-bearing transmembrane adapter protein called Fc receptor  $\gamma$ -chain (FcR $\gamma$ ). In addition, the GPI-anchored Fc $\gamma$ RIIIB is also present on the surface of human neutrophils. This molecule does not contain an ITAM-motif and is not associated with an ITAM-bearing adapter side chain; according to the current view it is functionally connected to Fc $\gamma$ RIIA (5, 6).

Murine neutrophils express a different set of activating Fc receptors including two low affinity (Fc $\gamma$ RIII and Fc $\gamma$ RIV) and one high affinity (Fc $\gamma$ RI) Fc receptors, all of which are associated with the ITAM-containing FcR $\gamma$  (5). Our previous findings indicated the critical but overlapping role of Fc $\gamma$ RIII and Fc $\gamma$ RIV in immune complex-dependent neutrophil activation (6). Subsequent *in vivo* studies revealed the importance of Fc $\gamma$ RIII and Fc $\gamma$ RIV for the development and progression of autoantibody-induced arthritis and autoimmune valvular carditis in the K/BxN serum transfer experimental model (7, 8).

As discussed above, all activating murine Fc $\gamma$  receptors form a complex with FcR $\gamma$ , which molecule does not contain a ligand binding domain (1). It is known that the lack of FcR $\gamma$  abrogates the cell surface expression of activating Fc $\gamma$  receptors and FcR $\gamma$ -deficiency leads to abolished Fc receptor-dependent neutrophil effector responses and protection from autoimmune arthritis (6, 9–13). However, due to the absence of the cell surface expression of activating Fc $\gamma$  receptors in FcR $\gamma$ -deficient mice, it remains unclear whether the sole function of FcR $\gamma$  is to enable the receptor expression or it is also actively involved in the signaling process through its ITAM tyrosines.

In prior *in vitro* structure-function studies, the role of ITAM tyrosine phosphorylation was demonstrated in serotonin secretion in a basophilic cell line suggesting the signaling function of FcR $\gamma$  ITAM tyrosines (14). It was also reported that the phosphorylation of the ITAM tyrosines is induced by the FcR $\gamma$ -associated Fc $\epsilon$ R stimulation in mast cells (15).

The functional role of these ITAM tyrosines was characterized using FcR $\gamma$ -deficient mice reconstituted with murine wild type and ITAM tyrosine mutant (Y65F/Y76F) transgenes. These findings suggested that the ITAM tyrosines are involved in degranulation, cytokine production, prostaglandin synthesis and passive systemic anaphylaxis in mast cells (16). In another genetic model for *in vivo* studies, human transgenic FcR $\gamma$  was expressed carrying mutated ITAM tyrosines on an FcR $\gamma$ -deficient genetic background (NOTAM mice) (17). While the surface expression of Fc receptors was not affected, the *in vivo* cytotoxicity critically depended on FcR $\gamma$  ITAM signaling (17). The uptake of immune complexes and the cross presentation of antigens was reported to be regulated by FcR $\gamma$  ITAM signaling in dendritic cells, while

MHC class II antigen presentation was ITAM-independent (18). In contrast to the first two reports suggesting the functions of FcR $\gamma$  ITAM tyrosines, recent mouse studies revealed that daratumumab, which is a monoclonal therapeutic antibody targeting CD38 that is highly expressed on the surface of some kinds of tumor cells, induces cancer cell death after its binding, which process occurs in NOTAM but not in FcR $\gamma$ -deficient mice after blocking Fc $\gamma$ RIIIB (19). In addition, Lehmann et al. showed that engineered chimeric antibodies instructed splenic dendritic cells to activate CD4- and CD8-positive T-cells through the FcR $\gamma$ -coupled Fc $\gamma$ RIV without the involvement of the ITAM tyrosines (20). Collectively, these recent reports indicated the existence of ITAM-independent *in vivo* functions of FcR $\gamma$ -coupled activating Fc receptors (19, 20). Therefore, further studies are needed to define the *in vivo* role of FcR $\gamma$  ITAM tyrosines.

Upon Fc receptor-stimulation of neutrophils, FcR $\gamma$  was reported to be phosphorylated and to recruit the Syk tyrosine kinase, which promotes activation of the distal signaling pathways and induces cellular effector responses (6, 21, 22). However, the functional role of the FcR $\gamma$  ITAM tyrosines has not been directly tested in neutrophils and neutrophil-dependent autoimmune diseases *in vivo*. Herein, we used a genetic approach to characterize the possible role of FcR $\gamma$  ITAM tyrosines in neutrophils and *in vivo* autoimmune arthritis. We demonstrated that FcR $\gamma$  ITAM tyrosines are required for the immune complex-dependent activation of neutrophils and the development and progression of experimental autoimmune arthritis.

## MATERIALS AND METHODS

### Animals

FcR $\gamma$ -deficient (*Fcer1g*<sup>tm1Rav/tm1Rav</sup>, referred to as FcR $\gamma$  KO) mice were purchased from Taconic Farms (Hudson, NY, USA) (10). Animals expressing the wild type and the ITAM tyrosine mutant FcR $\gamma$  (where tyrosines at positions 65 and 76 were replaced by phenylalanines) were described previously and were crossed with FcR $\gamma$  KO mice (referred to as FcR $\gamma$  KO + WT FcR $\gamma$  Tg and FcR $\gamma$  KO + YF FcR $\gamma$  Tg animals, respectively) (16). To augment the expression of the transgenic wild type and mutant FcR $\gamma$  chain, the mice were crossed to obtain homozygous, double transgenic animals (referred to as FcR $\gamma$  KO + 2x WT FcR $\gamma$  Tg and FcR $\gamma$  KO + 2x YF FcR $\gamma$  Tg mice, respectively). Single and double transgenic animals were differentiated by quantitative PCR. Mice carrying the KRN T-cell-receptor transgene were maintained in heterozygous form by mating with C57BL/6 mice (23). All transgenic mice were backcrossed to the C57BL/6 genetic background. Genotyping was performed by allele-specific PCR.

Wild type control C57BL/6 mice were purchased from Charles River or the Hungarian National Institute of Oncology (Budapest, Hungary). NOD mice, as well as a congenic strain carrying the CD45.1 allele on the C57BL/6 genetic background (B6.SJL-*Ptprc*<sup>cl</sup>) were purchased from the Jackson Laboratory.

Mice were kept in individually ventilated cages (Tecniplast) in a conventional facility. All animal experiments were approved by the Animal Experimentation Review Board of the Semmelweis University.

**Abbreviations:** FcR $\gamma$ , Fc receptor  $\gamma$ -chain; IC, Immune complex; ITAM, Immunoreceptor tyrosine-based activation motif; FcR, Fc receptor; GPI, Glycosylphosphatidylinositol; PCR, Polymerase chain reaction; PMA, Phorbol myristate acetate; WT, Wild type.

Bone marrow chimeras were generated by intravenous injection of unfractionated bone marrow cells into recipients carrying the CD45.1 allele on the C57BL/6 genetic background, which were lethally irradiated before by 11 Gy from a  $^{137}\text{Cs}$  source using a Gamma-Service Medical (Leipzig, Germany) D1 irradiator. 4 weeks after transplantation, peripheral blood samples were stained for Ly6G and CD45.2 (Clones 1A8 and 104, respectively; both from BD Biosciences) and analyzed by a BD Biosciences FACSCalibur flow cytometer as previously described (21).

### K/B $\times$ N Serum-Transfer Arthritis

Mice carrying the KRN T-cell receptor transgene on the C57BL/6 genetic background were mated with NOD mice to obtain transgene-positive (arthritic) K/B $\times$ N and transgene-negative (control) B $\times$ N mice (23, 24). The presence of the transgene was determined by allele-specific PCR and confirmed by phenotypic assessment. Blood was taken by retroorbital bleeding and sera from arthritic and control mice were pooled separately.

Arthritis was induced by a single intraperitoneal injection of 400  $\mu\text{l}$  K/B $\times$ N (arthritic) or B $\times$ N (control) serum into intact mice or bone marrow chimeras, followed by daily assessment of arthritis severity for 2 weeks as described (24–26). Visible clinical signs were scored on a 0–10 scale by two investigators blinded for the origin and treatment of the mice. Ankle thickness was measured by a spring-loaded caliper (Kroeplin). For histological analysis, mice were sacrificed on Day 8, their fore limbs were fixed in 4% paraformaldehyde, decalcified (Osteomoll, Merck Millipore) dehydrated, embedded in paraffin, sectioned at 9  $\mu\text{m}$  thickness and stained with hematoxylin and eosin.

### Isolation and Activation of Neutrophils

Mouse neutrophils were isolated from the bone marrow of the femurs and tibias of intact mice or chimeras by hypotonic lysis followed by Percoll (GE Healthcare) gradient centrifugation using sterile and endotoxin-free reagents as described (25–27). Cell surface Fc $\gamma$ RIV expression was detected by an anti-Fc $\gamma$ RIV antibody (Clone 9E9; a gift from Prof. Jeffrey V. Ravetch). A secondary staining with FITC labeled anti-Armenian and Syrian hamster antibodies (Clones G70-204 and G94-56; BD Biosciences) was performed.

Neutrophils were kept at room temperature in  $\text{Ca}^{2+}$ - and  $\text{Mg}^{2+}$ -free medium until use and prewarmed to 37°C prior to activation. Neutrophil assays were performed at 37°C in HBSS supplemented with 20 mM HEPES, pH 7.4. To obtain immobilized immune complex-coated surfaces, human lactoferrin (LFR; Sigma-Aldrich) was either bound directly to regular Nunc MaxiSorp F96 (Thermo Fisher) plates (for superoxide release and degranulation measurements) or covalently linked to poly-L-lysine-coated 24-well tissue culture plates (for spreading assays) and then treated with rabbit anti-LFR IgG (Sigma-Aldrich) as described (6). Superoxide release by neutrophils was followed by a cytochrome c reduction test from 100  $\mu\text{l}$  aliquots of  $4 \times 10^6/\text{ml}$  cells plated on immobilized immune complexes or on 10% fetal cow serum (FCS) in the presence of PMA as described (25). The release of gelatinase was determined by gelatinase zymography as

previously described (6). Spreading of the cells was followed by phase contrast microscopy.

### Biochemical Studies

For analysis of protein contents, neutrophils were lysed in 100 mM NaCl, 30 mM Na-HEPES (pH 7.4), 20 mM NaF, 1 mM Na-EGTA, 1% Triton X-100, 1 mM benzamidine, freshly supplemented with 0.1 U/ml Aprotinin, 1:100 Mammalian Protease Inhibitor Cocktail, 1:100 Phosphatase Inhibitor Cocktail 2, 1 mM PMSF and 1 mM  $\text{Na}_3\text{VO}_4$  (all from Sigma-Aldrich). After removal of insoluble material, lysates were boiled in sample buffer. Whole cell lysates were run on SDS-PAGE and immunoblotted using antibodies against FcR $\gamma$  (Host: rabbit; Upstate) or  $\beta$ -actin (Clone AC-74; Sigma-Aldrich) and by peroxidase-labeled secondary antibodies (GE Healthcare). The signal was developed using the ECL system (GE Healthcare) and exposed to X-ray films.

### Presentation of the Data and Statistical Analysis

Experiments were performed the indicated number of times. Quantitative graphs and kinetic curves show mean and SEM from all independent *in vitro* experiments or from all individual mice from the indicated number of experiments. Statistical analyses were carried out by the STATISTICA software using two-way (factorial) ANOVA, with treatment and genotype being the two independent variables. In case of kinetic assays, area under the curve (AUC) was used for statistical analysis. *P* values below 0.05 were considered statistically significant.

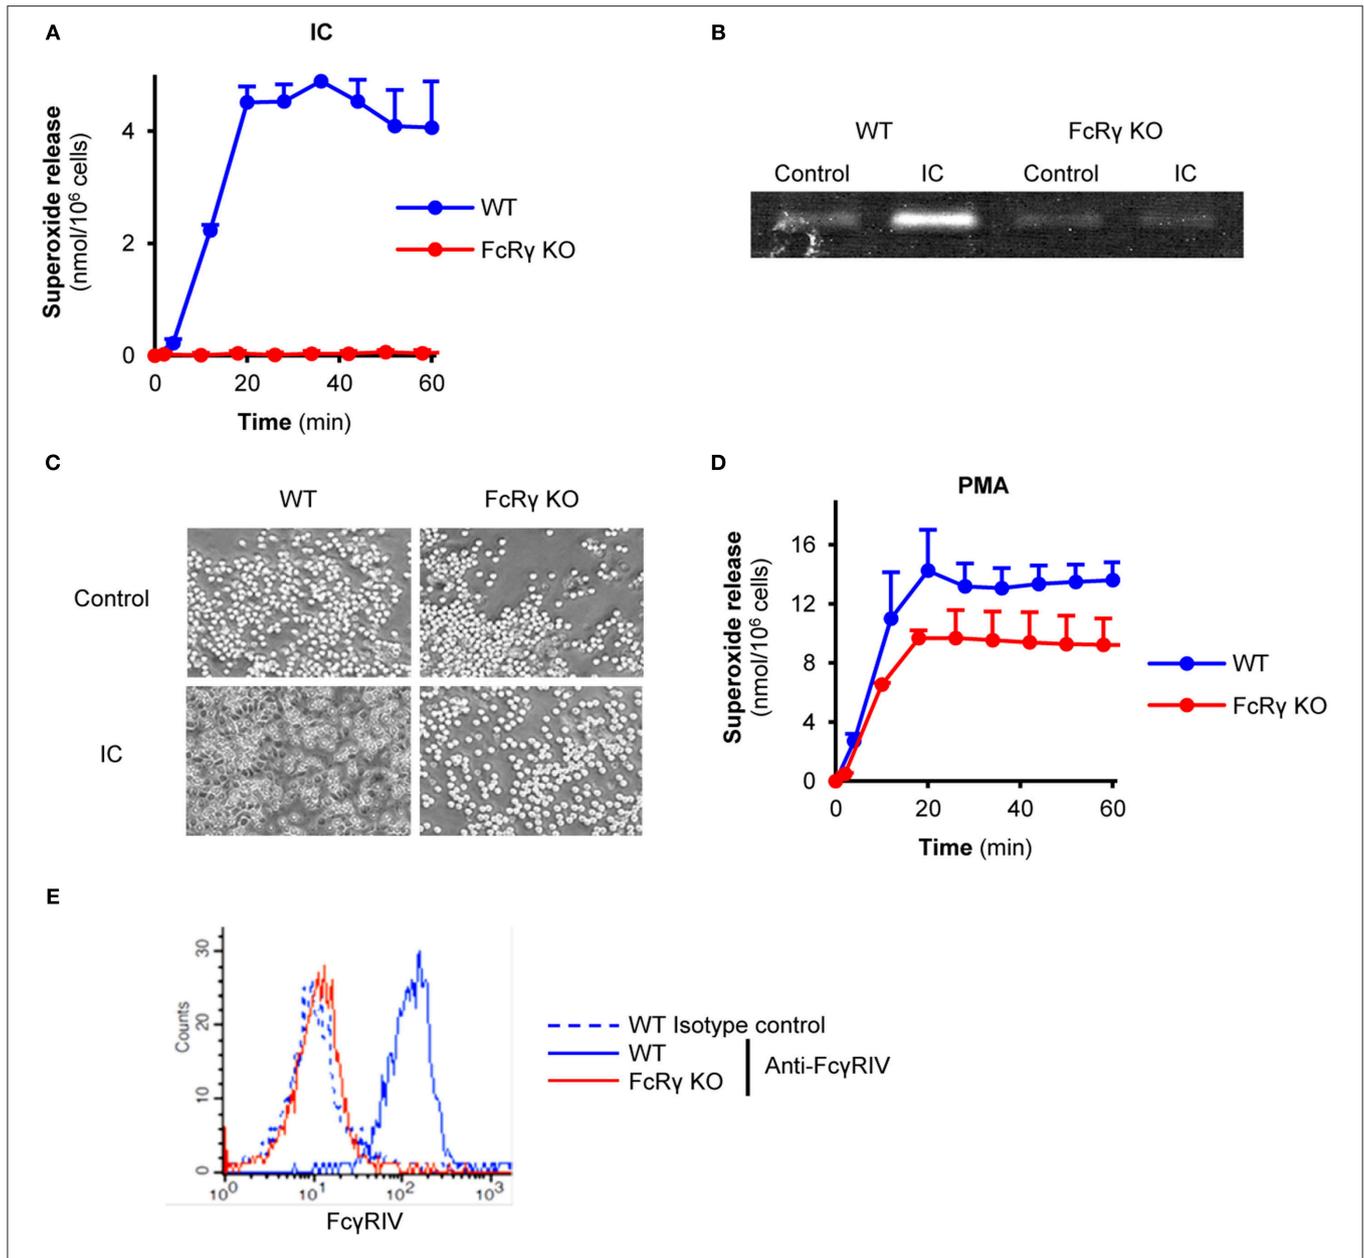

## RESULTS

### FcR $\gamma$ -Deficient Neutrophils Have Impaired Immune Complex-Mediated Cell Responses and Lack Activating Fc Receptors From the Cell Surface

First, we characterized the phenotype of the FcR $\gamma$ -deficient neutrophils. When plating on immobilized immune complex surfaces, freshly isolated wild type mouse neutrophils were able to produce superoxide, while in the absence of the FcR $\gamma$  the cell response was abolished (Figure 1A;  $P = 1.3 \times 10^{-4}$ ). In line with this finding, FcR $\gamma$ -deficient neutrophils were unable to release the granule marker gelatinase or perform cell spreading (Figures 1B,C;  $P = 2.6 \times 10^{-4}$  and  $P = 1.4 \times 10^{-4}$ ). Meanwhile, the absence of the adaptor chain did not affect Fc receptor-independent superoxide production triggered by PMA compared to wild type cells (Figure 1D;  $P = 0.81$ ). However, the activating, FcR $\gamma$ -associated Fc $\gamma$  receptor IV was found to be absent from the cell surface of FcR $\gamma$ -deficient neutrophils (Figure 1E;  $P = 4.4 \times 10^{-5}$ ).

### Restoration of FcR $\gamma$ -Expression in Neutrophils by Wild Type and ITAM Mutant FcR $\gamma$

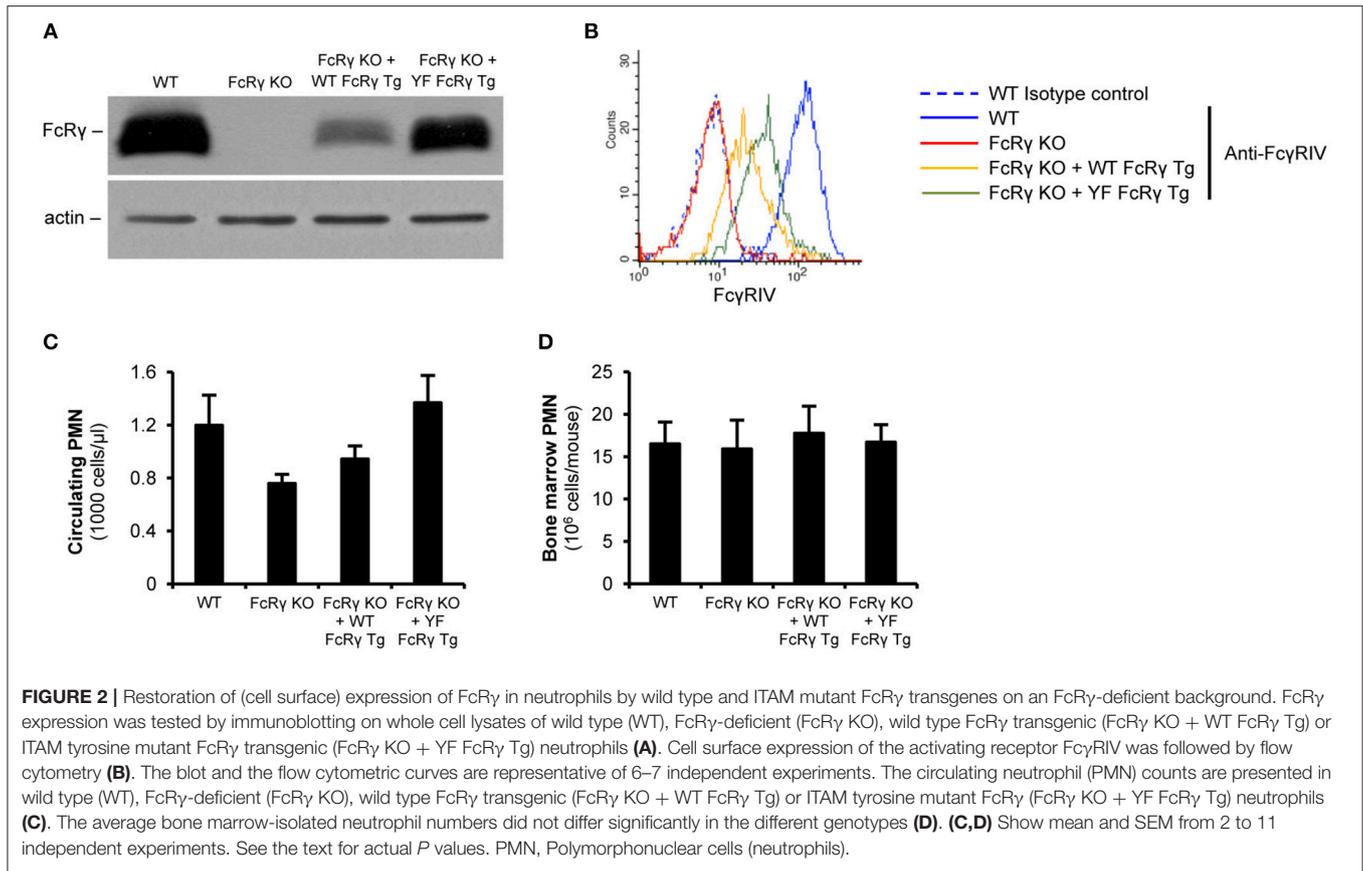

For investigating the role of the intracellular ITAM tyrosines in various cell responses, we re-expressed wild type or ITAM

**FIGURE 1** | Impaired effector responses and activating Fc receptor-expression in FcR $\gamma$ -deficient neutrophils. Wild type (WT) and FcR $\gamma$ -deficient (FcR $\gamma$  KO) neutrophils were plated on immobilized immune complexes and their superoxide release (**A**), gelatinase degranulation (**B**), and spreading (**C**) was followed. The ability of FcR $\gamma$  KO cells to produce superoxide anions was tested by PMA stimulation (at a 100 nM concentration) (**D**). Neutrophil cell surface Fc $\gamma$ RIV expression was detected by flow cytometry (**E**). The gelatinase zymogram, the photos and the flow cytometric curves are representative of 3–7 independent experiments. Kinetic curves in (**A**,**D**) show mean and SEM of 3 independent experiments. Control data points were subtracted. See the text for actual *P* values. IC, Immune complex; PMA, Phorbol myristate acetate.

tyrosine mutant FcR $\gamma$  in mice on an FcR $\gamma$ -deficient background. According to the immunoblot results, neutrophils from the wild type and the ITAM tyrosine mutant FcR $\gamma$  transgenic mice could produce the protein (**Figure 2A**; the expression level was 24% and 68% of the original wild type level, respectively;  $P = 2.2 \times 10^{-3}$  for FcR $\gamma$  KO + WT FcR $\gamma$  Tg vs. FcR $\gamma$  KO). As a consequence, the activating Fc $\gamma$  receptor IV appeared on the cell surface of the two different transgenic neutrophil populations (**Figure 2B**; the

expression level was 25 and 43% of the maximum, respectively;  $P = 0.026$  for FcR $\gamma$  KO + WT FcR $\gamma$  Tg vs. FcR $\gamma$  KO). We further analyzed the neutrophil counts in the periphery or in the bone marrow in wild type, FcR $\gamma$ -deficient, wild type and ITAM mutant FcR $\gamma$ -expressing mice and we did not detect significant differences in the sizes of the granulocyte populations (**Figures 2C,D**;  $P = 0.09$  and  $P = 0.97$ , respectively). This indicated that transgenic re-expression of wild type and ITAM

tyrosine mutant FcR $\gamma$  did not interfere with neutrophil survival and viability.

### FcR $\gamma$ ITAM Tyrosines Are Critical for Immune Complex-Mediated Neutrophil Cell Responses

Compared to FcR $\gamma$ -deficient neutrophils, re-expression of the wild type FcR $\gamma$  could partially restore the Fc receptor-mediated release of superoxide, while this response was totally blocked in connection with ITAM tyrosine mutant FcR $\gamma$ -bearing cells (Figure 3A;  $P = 0.017$  for FcR $\gamma$  KO + WT FcR $\gamma$  Tg vs. FcR $\gamma$  KO + YF FcR $\gamma$  Tg and  $P = 0.75$  for FcR $\gamma$  KO + YF FcR $\gamma$  Tg vs. FcR $\gamma$  KO). The same essential role of these tyrosines could be observed in connection with gelatinase degranulation and cell spreading (Figures 3B,C;  $P = 0.04$  for FcR $\gamma$  KO + WT FcR $\gamma$  Tg vs. FcR $\gamma$  KO + YF FcR $\gamma$  Tg and  $P = 0.02$  for FcR $\gamma$  KO + WT FcR $\gamma$  Tg vs. FcR $\gamma$  KO + YF FcR $\gamma$  Tg, respectively). In contrast to immune complex-triggered conditions, PMA induced a robust superoxide production in all genotypes (Figure 3D;  $P = 0.90$ ).

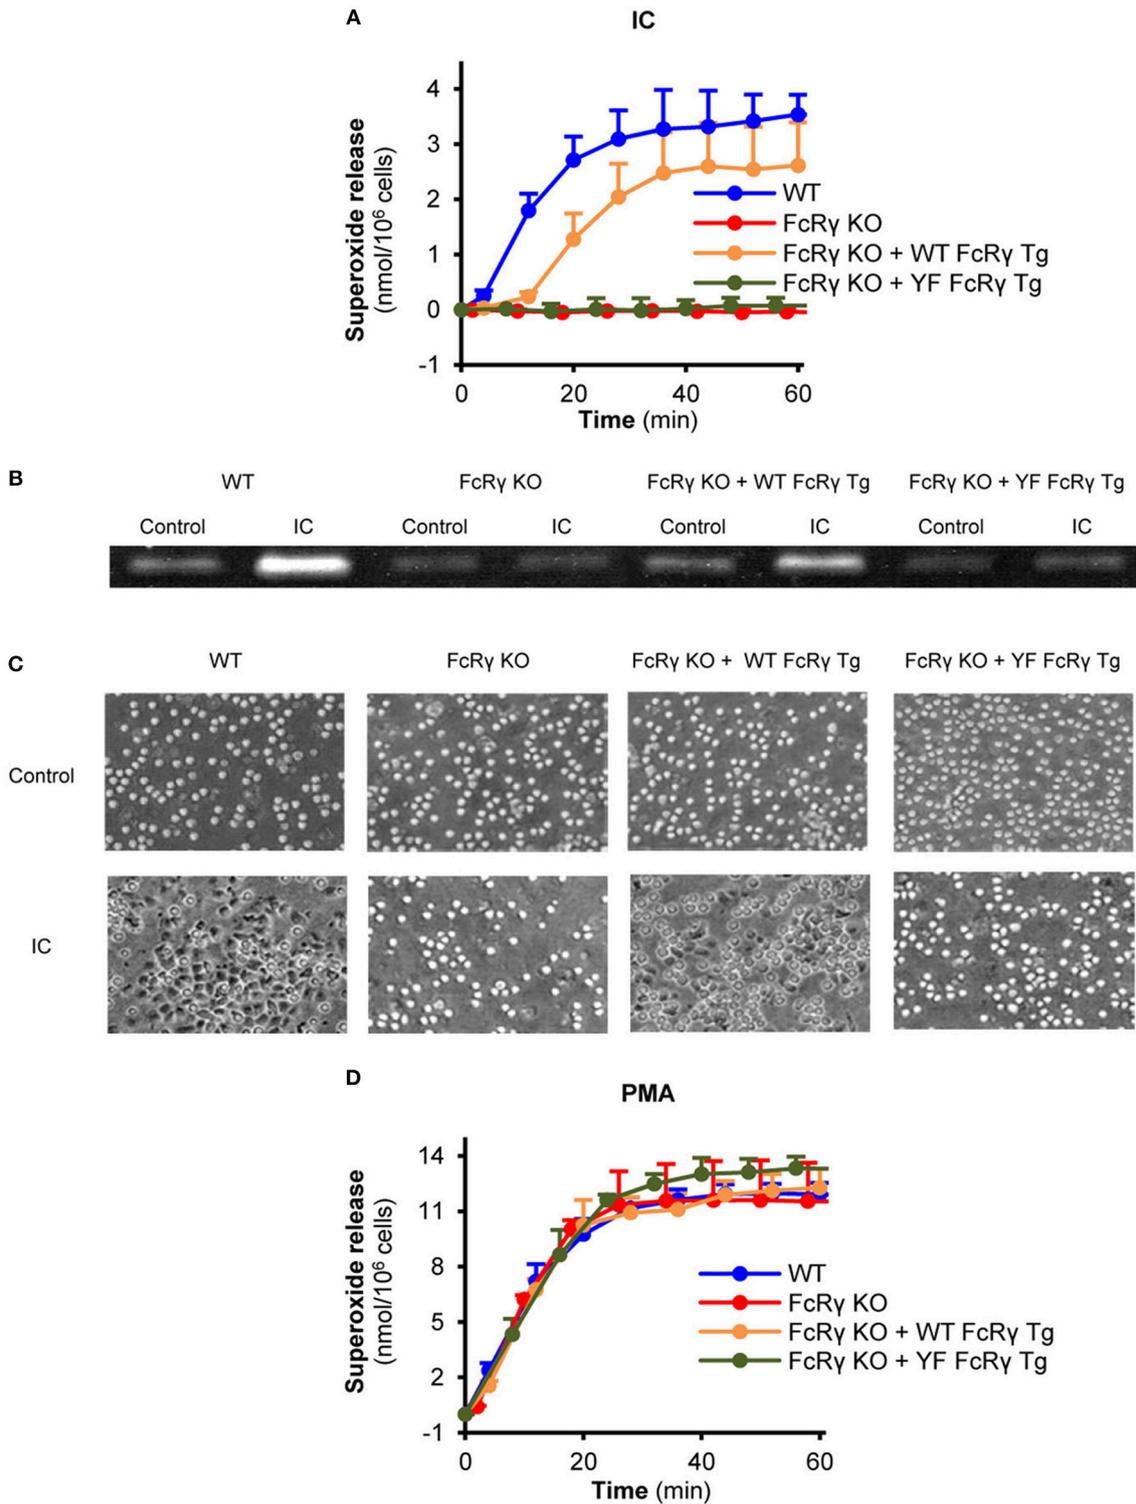

### Essential Role of FcR $\gamma$ ITAM Tyrosines in Arthritis Development

For the *in vivo* studies, besides using intact mice, we also generated bone marrow, radiation chimeras in order to investigate the role of the FcR $\gamma$  ITAM tyrosines in the myeloid

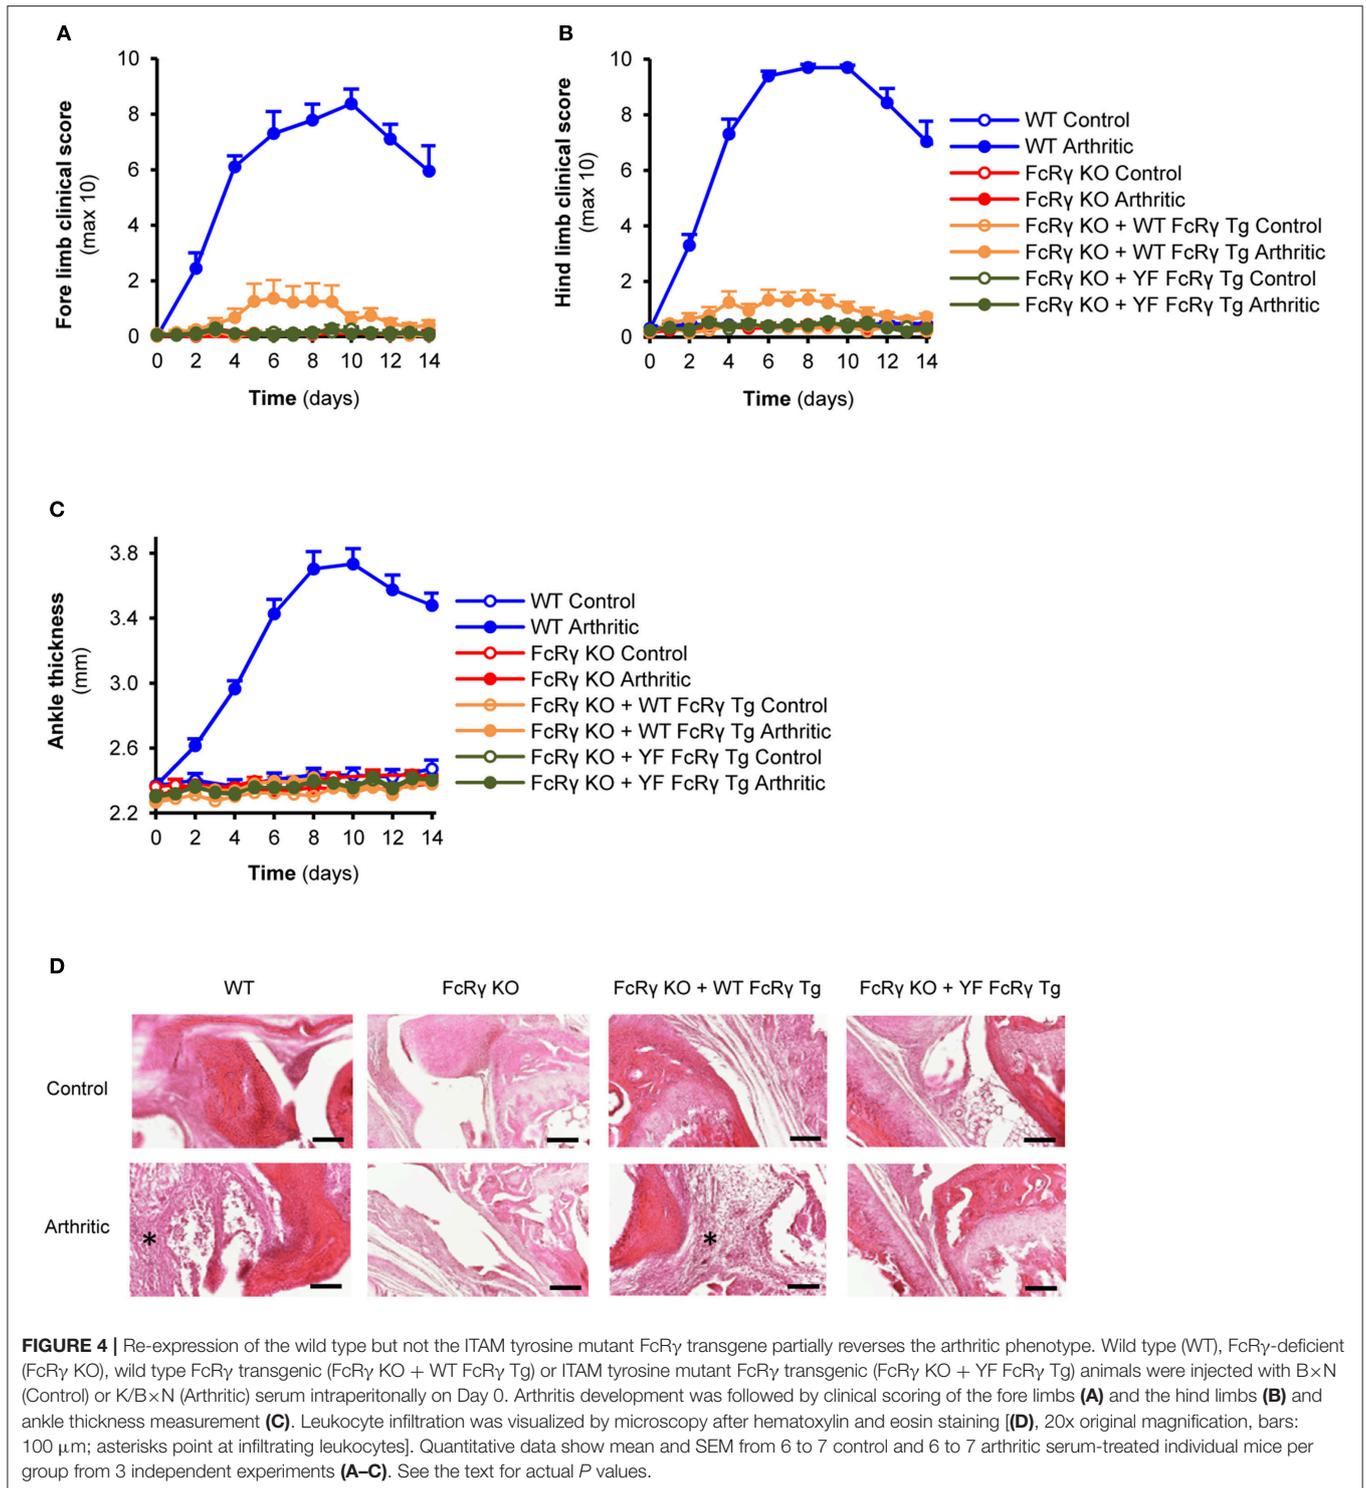

compartment. In general, we did not see substantial differences between the arthritic phenotypes of the intact animals and the bone marrow chimeras. When receiving K/BxN serum, a small, but significant visible inflammation appeared on the fore and hind limbs of the wild type FcR $\gamma$  transgenic mice that was totally missing from the animals with the ITAM mutant FcR $\gamma$  (Figures 4A,B;  $P = 0.034$  for FcR $\gamma$  KO + WT FcR $\gamma$  Tg vs. FcR $\gamma$  KO + YF FcR $\gamma$  Tg and  $P = 0.61$  for FcR $\gamma$  KO + YF FcR $\gamma$  Tg vs. FcR $\gamma$  KO in connection with the fore limbs;  $P = 0.012$  for FcR $\gamma$  KO + WT FcR $\gamma$  Tg vs. FcR $\gamma$  KO + YF FcR $\gamma$  Tg and  $P = 0.87$  for FcR $\gamma$  KO + YF FcR $\gamma$  Tg vs. FcR $\gamma$  KO in connection with the hind limbs). However, we could not detect ankle thickness changes in the wild type FcR $\gamma$  transgenic mice despite of a massive leukocyte infiltration to the joints seen on the histological sections in contrast to ITAM tyrosine mutant FcR $\gamma$  expressing animals (Figures 4C,D;  $P = 0.27$  for FcR $\gamma$  KO + WT FcR $\gamma$  Tg vs. FcR $\gamma$  KO in Panel C).

### Augmentation of the Expression of the Transgenic Wild Type but not the ITAM Mutant FcR $\gamma$ Enhances Arthritis Severity

For raising the expression level of the wild type and ITAM mutant transgenic FcR $\gamma$ , we crossed the single transgenic (hemizygous) mice to obtain double transgenic (homozygous) animals. As shown in Figure 5A, this process resulted in an obvious enhancement in the levels of FcR $\gamma$  in neutrophils of the

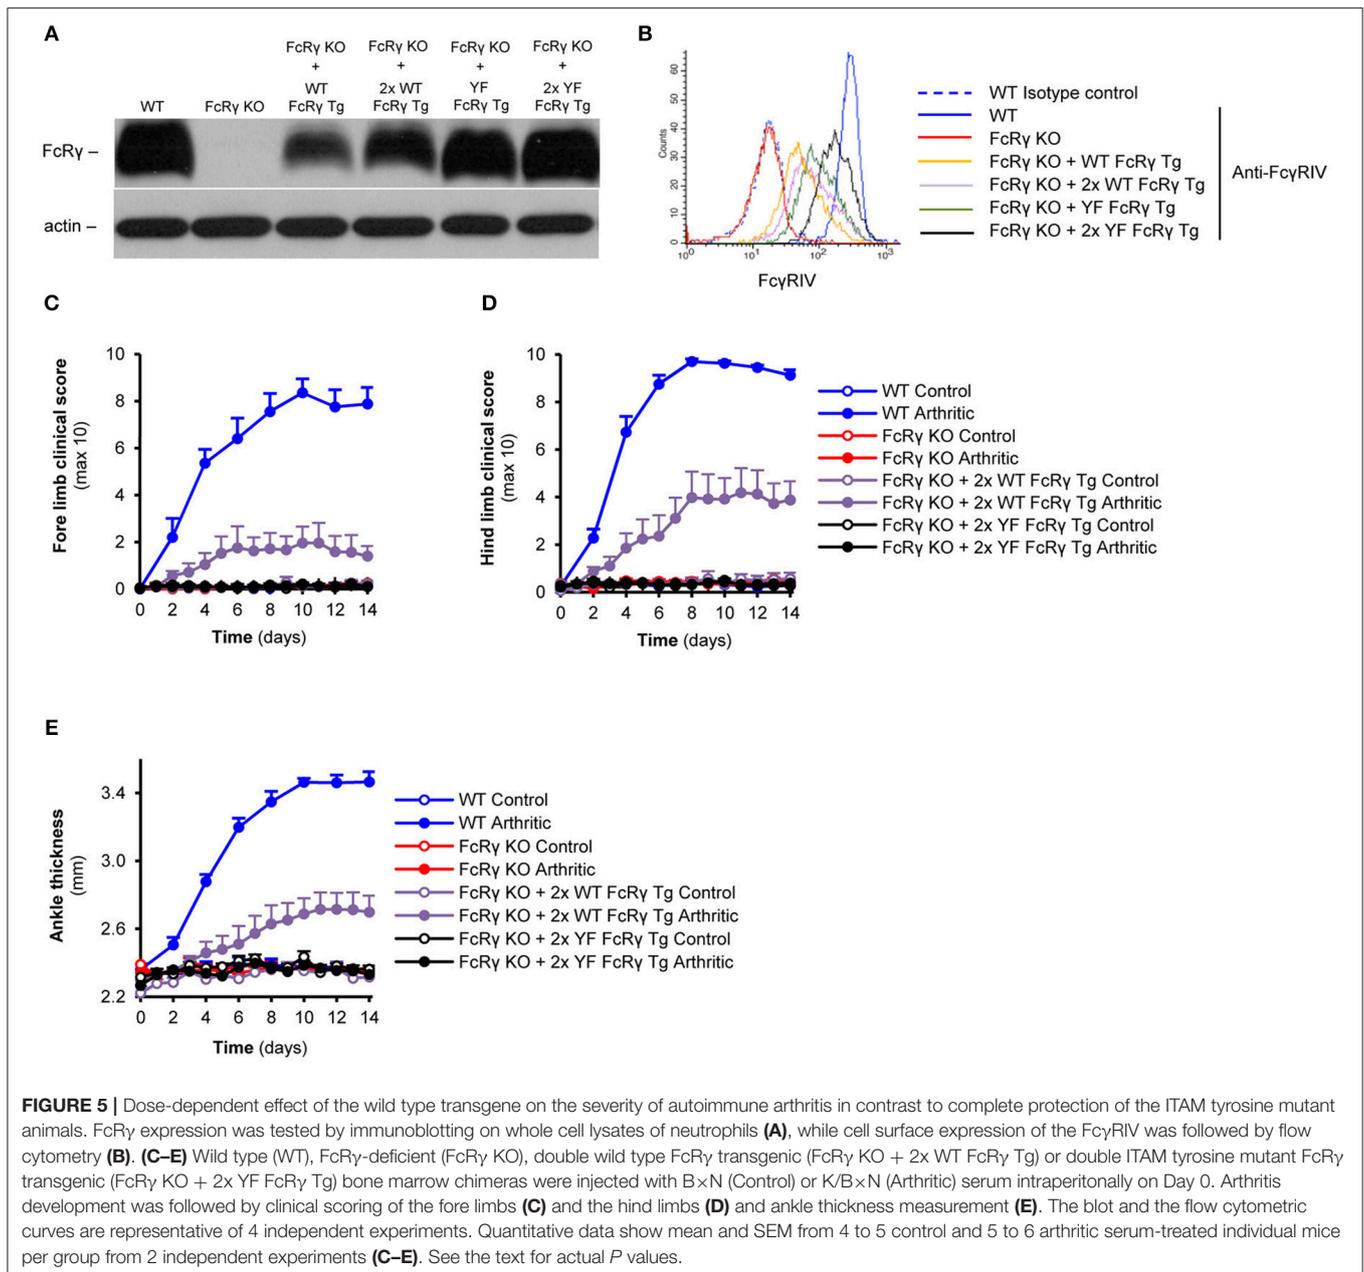

**FIGURE 3 |** Critical role of the intracellular FcR $\gamma$  ITAM tyrosines in mediating neutrophil cell responses *in vitro*. Wild type (WT), FcR $\gamma$ -deficient (FcR $\gamma$  KO), wild type FcR $\gamma$  transgenic (FcR $\gamma$  KO + WT FcR $\gamma$  Tg) or ITAM tyrosine mutant FcR $\gamma$  transgenic (FcR $\gamma$  KO + YF FcR $\gamma$  Tg) neutrophils were plated on immobilized immune complex surfaces and their superoxide release **(A)**, gelatinase release **(B)** and cell spreading **(C)** were detected. The functionality of all genotypes was tested by PMA stimulation **(D)**. Kinetic curves in **(A,D)** represent mean and SEM from 3 independent experiments. The gelatinase zymogram and the photos are representative of 3 independent experiments. See the text for actual *P* values. IC, Immune complex; PMA, Phorbol myristate acetate.

homozygous transgenic mice compared to that of the hemizygous ones. The augmentation also appeared in the changes of the cell surface Fc $\gamma$  receptor IV-expression (**Figure 5B**). Double transgenic wild type FcR $\gamma$  bone marrow chimeras showed a robust arthritic phenotype on all limbs, while the double

transgenic ITAM tyrosine mutant FcR $\gamma$  chimeras were totally protected from arthritis development (**Figures 5C,D**;  $P = 0.04$  for FcR $\gamma$  KO + 2x WT FcR $\gamma$  Tg vs. FcR $\gamma$  KO + 2x YF FcR $\gamma$  Tg and  $P = 0.70$  for FcR $\gamma$  KO + 2x YF FcR $\gamma$  Tg vs. FcR $\gamma$  KO in connection with the fore limbs;  $P = 9.2 \times 10^{-3}$

for FcRγ KO + 2x WT FcRγ Tg vs. FcRγ KO + 2x YF FcRγ Tg and  $P = 0.96$  for FcRγ KO + 2x YF FcRγ Tg vs. FcRγ KO in connection with the hind limbs). Double wild type FcRγ transgenic bone marrow chimeras also showed a significant ankle thickening compared to the homozygous ITAM mutant FcRγ transgenic bone marrow chimeras (Figure 5E;  $P = 0.01$  for FcRγ KO + 2x WT FcRγ Tg vs. FcRγ KO + 2x YF FcRγ Tg and  $P = 0.96$  for FcRγ KO + 2x YF FcRγ Tg vs. FcRγ KO).

Our results indicate an essential role for the FcRγ ITAM tyrosines in immune complex-triggered neutrophil cell responses and experimental arthritis.

## DISCUSSION

Our results show that FcRγ is critical to stabilize the expression of the activating Fcγ receptors in the plasma membrane and reveals that this function is independent from the presence of its ITAM tyrosines (Figure 2). Former *in vitro* studies demonstrated the importance of a non-covalent, salt bridge-mediated interaction between the Fcγ receptor and the ITAM-containing side chain in the endoplasmic reticulum to prevent the degradation of the complex and enable the transfer of the complex to the Golgi apparatus (28). It is thought that this process is involved in the regulation of the cell surface expression of Fcγ receptors.

Although our findings fit into this picture, further studies will be needed to characterize the intracellular mechanisms which stabilize and prevent the complex from degradation.

As a key observation, our structure-function studies revealed the importance of Fc $\gamma$  ITAM tyrosines in immune complex-mediated neutrophil effector functions including the release of reactive oxygen species, degranulation and spreading. These findings are in accordance with previous studies of basophilic cell lines, in which the role of ITAM tyrosines was shown in Fc $\gamma$ RIIA signaling, and in mast cells, where cell functions were abrogated after IgE-dependent stimulation (14, 16).

*In vivo* studies using murine wild type and ITAM tyrosine mutant transgenes suggested that the ITAM tyrosines are involved in degranulation, cytokine production, prostaglandin synthesis, and passive systemic anaphylaxis in mast cells (16). Even though the early *in vivo* studies on the NOTAM mouse carrying ITAM mutant Fc $\gamma$  indicated the ITAM-dependence of *in vivo* cytotoxicity, uptake of immune complexes, and the cross presentation of antigens in dendritic cells (17, 18), recent papers revealed that daratumumab-induced cancer cell death (after blocking Fc $\gamma$ RIIB) and the splenic dendritic cell-mediated activation of CD4- and CD8-positive T cells occur in an Fc $\gamma$  ITAM-independent manner (19, 20). In connection to this, our *in vivo* studies indicate that Fc $\gamma$  ITAM signaling is essential for mediating the initiation and progression of autoimmune arthritis. However, further studies are needed to test whether—similarly to dendritic cells—ITAM independent signaling mechanisms are also involved in other *in vivo* functions of neutrophils. It would be also informative to test the role of the ITAM tyrosines of Fc $\gamma$  in other autoantibody-mediated disease models in the future to further support our findings with experimental arthritis.

*In vitro* and *in vivo* studies monitoring the phosphorylation state of ITAM tyrosines indicated that both ITAM tyrosines are phosphorylated upon stimulation, but the carboxy-terminal tends to be dephosphorylated much faster in mast cells (15). However, it is not known how the phosphorylation state of the two tyrosines is regulated in neutrophils.

It should be noted that not only Fc $\gamma$ RIII and Fc $\gamma$ RIV—the receptor that is alone sufficient to induce arthritis (7)—, but other receptors also are associated with Fc $\gamma$ , including Paired Immunglobulin-like receptor-A (PIR-A), Leukocyte immunglobulin-like receptor 1C (LILR1C), Osteoclast-associated receptor (OSCAR), T cell-interacting, activating receptor on myeloid cells-1 (TARM1), Dectin-2 or some  $\beta$  integrins in neutrophils (29–36). Further studies are needed whether the ligand binding or crosslinking of these receptors require the function of the Fc $\gamma$  ITAM tyrosines to enable the expression and induction of cellular responses.

As shown in **Figures 2** and **5**, the expression levels of the wild type and the Fc $\gamma$  ITAM mutant transgenic neutrophils are different. The presence of the complex between the ITAM-containing molecule and the Fc $\gamma$  receptor has been reported in the endoplasmic reticulum, which is likely the cellular organism where the stability of the complex and the degradation of the components is actively regulated that

may require the presence of the ITAM tyrosines (28). It is also possible that the copy numbers of the two transgenes are different. A third possibility is that different enhancer and silencer elements are involved in the regulation of the expression of the two transgenes as they may not be present at the same place in the genome. Most importantly, despite of the higher level, ITAM mutant Fc $\gamma$  was not able to restore neutrophil effector responses and reverse the development of autoimmune arthritis, which further support our conclusions.

Compared to the hemizygous animals, the double transgenic wild type Fc $\gamma$  mice could reverse more effectively the development of autoimmune arthritis on the Fc $\gamma$ -deficient background, indicating that the disease progression is highly dependent on the level of the signaling molecule. This can be the explanation of why the ankle thickness was not significantly changed, while the increase in the more sensitive clinical score was significant and the immune cell infiltration was massive and robust in the single wild type Fc $\gamma$  ITAM transgenic animals.

As the absence of Fc $\gamma$  was not required for neutrophil migration in experimental arthritis, it can be hypothesized that Fc $\gamma$  ITAM tyrosines are also not involved in the accumulation of neutrophils at the site of inflammation (37). These tyrosines could rather have a role in mediating immune complex-triggered responses at the site of tissue damage as we showed it in connection with several other molecules involved in neutrophil Fc $\gamma$  receptor signaling (21, 24, 26).

Besides neutrophils, other cell types like macrophages, mast cells or platelets have been indicated in the pathogenesis of experimental arthritis (38–41). It would be interesting to test the role of the ITAM tyrosines of Fc $\gamma$  in these cell populations in joint inflammation. Collectively, our studies revealed the critical role of Fc $\gamma$  ITAM tyrosines in immune complex-mediated activation of neutrophils and the development and progression of autoantibody-induced autoimmune arthritis. Importantly, our studies provide the first direct *in vivo* evidence for the role of Fc $\gamma$  ITAM tyrosines in a neutrophil-dependent *in vivo* arthritis model. Understanding these molecular mechanisms can serve as new therapeutic targets in the treatment of some autoimmune diseases in the future (e.g., by the development of molecules which may mask the ITAM tyrosines of Fc $\gamma$ ).

## AUTHOR CONTRIBUTIONS

TN, AM, and ZJ designed the work, interpreted the results and wrote the paper. TN, KF, MS, PA, and ZJ performed the experiments and analyzed the data. TS developed and provided the wild type and ITAM mutant Fc $\gamma$  transgenic mouse strains.

## FUNDING

Lendület program of the Hungarian Academy of Sciences (LP2014-4/2018 to ZJ), the National Research, Development and Innovation Office (NVKP\_16-2016-1-0039 to AM and ZJ), the Ministry of National Economy (VEKOP-2.3.2-16-2016-00002 to AM and ZJ), the European Union's H2020 IMI2 program

(RTCure; grant No. 777357 to AM) the Higher Education Institutional Excellence Program of the Ministry of Human Capacities in Hungary within the framework of the Molecular Biology thematic program of the Semmelweis University (to AM and ZJ) and the János Bolyai Research Scholarship of the Hungarian Academy of Sciences (to KF).
